68 **Abstract**

69 CD19-targeting chimeric antigen receptors (CARs) with CD28 and CD3 $\zeta$  signaling domains  
70 have been approved by the US FDA for treating B cell malignancies. Mutation of immunoreceptor  
71 tyrosine-based activation motifs (ITAMs) in CD3 $\zeta$  generated a single-ITAM containing 1XX CAR,  
72 which displayed superior anti-tumor activity in a leukemia mouse model. Here we investigated  
73 whether the 1XX design could enhance therapeutic potency against solid tumors. We constructed  
74 both CD19- and AXL-specific 1XX CARs and compared their *in vitro* and *in vivo* functions with  
75 their wild type (WT) counterparts. 1XX CARs showed better anti-tumor efficacy in both  
76 pancreatic and melanoma mouse models. Detailed analysis revealed that 1XX CAR-T cells  
77 persisted longer *in vivo* and had a higher percentage of central memory cells. With fluorescence  
78 resonance energy transfer (FRET)-based biosensors, we found that decreased ITAM numbers in  
79 1XX resulted in similar 70-kDa zeta-chain associated protein (ZAP70) activation, while 1XX  
80 induced higher Ca<sup>2+</sup> elevation and faster extracellular signal-regulated kinase (Erk) activation than  
81 WT CAR. Thus, our results confirmed the superiority of 1XX against two targets in different solid  
82 tumor models and shed light on the underlying molecular mechanism of CAR signaling, paving  
83 the way for the clinical applications of 1XX CARs against solid tumors.

84

## 85 Introduction

86 The adoptive transfer of chimeric antigen receptor (CAR)-T cells has achieved great  
87 success in treating hematological malignancies and the US FDA has approved four CD19-specific  
88 CAR-T products and two products targeting BCMA.<sup>1,2</sup> On the other hand, it is generally  
89 recognized that the application of CAR-T in solid tumors has been impeded by many factors,  
90 including a lack of tumor-exclusive antigen, inefficient tumor trafficking and immunosuppressive  
91 tumor microenvironment.<sup>3</sup> Various strategies have been developed in combination of CAR to  
92 overcome these hurdles, such as co-expression of cytokines,<sup>4,5</sup> secretion of scFv against PD-1,<sup>6</sup>  
93 secretion of BiTEs to recruit bystander T cells<sup>7</sup> and the use of IL-7/CCL-19 to increase trafficking.<sup>8</sup>  
94 However, the CAR design itself may still not be optimized to fully harness the power of T cells.

95 In addition to the activation signals from a T cell receptor (TCR), T cells integrate signals  
96 from costimulatory/coinhibitory receptors and cytokine receptors through a complex signaling  
97 network to direct multiple functions, such as proliferation, cytotoxicity, cytokine secretion and  
98 differentiation.<sup>9</sup> These functions need to be balanced to achieve optimal long-term anti-tumor  
99 effects. After antigen binding, CD28-based second-generation CARs transduce signals through the  
100 costimulatory domain from CD28 and the activation domain from CD3 $\zeta$ , which comprises three  
101 immunoreceptor tyrosine-based activation motifs (ITAMs). Both pathways highly depend on the  
102 activity of Lck kinase. Each ITAM in CD3 $\zeta$  after being phosphorylated by Lck recruits ZAP70  
103 kinase so that ZAP70 can be phosphorylated by Lck.<sup>10</sup> ZAP70 activation further phosphorylates  
104 adaptor LAT at the membrane, which forms a signaling network with various proteins, such as  
105 Grb2/Sos and PLC $\gamma$ . PLC $\gamma$  catalyzes the formation of two important second messengers, DAG and  
106 IP3.<sup>11</sup> IP3 binds to receptors at the ER to release large amount of Ca<sup>2+</sup>, while both DAG and  
107 Grb2/Sos could activate Erk through Ras.<sup>12,13</sup> Meanwhile, after being phosphorylated by Lck, the

108 CD28 cytosolic domain can recruit and activate PI3K.<sup>14</sup> PIP3 produced by PI3K binds to the PH  
109 domain of Itk, recruiting Itk to the membrane. Itk can directly interact with PLC $\gamma$  and activate it.<sup>15</sup>  
110 Thus, both pathways can modulate downstream Ca<sup>2+</sup> and Erk activities.

111 A single ITAM-containing 1XX CAR design with calibrated activation potential has been  
112 shown to have superior anti-tumor activity in a leukemia mouse model by balancing activation and  
113 costimulatory signals.<sup>16</sup> Here we investigated whether this design benefits CAR-T therapy against  
114 solid tumors. We also quantified the molecular activities in CAR-T cells with high temporal  
115 resolution by fluorescence resonance energy transfer (FRET) biosensors. Based on the importance  
116 of the signaling molecules and the availability of biosensors, we chose ZAP70, Ca<sup>2+</sup> and Erk  
117 biosensors<sup>17-19</sup> to reveal differences in signaling dynamics induced by 1XX compared to WT CAR.

## 118 **Results**

### 119 **CD19-1XX CAR-T cells had lower cytotoxicity against Panc-1 cells *in vitro***

120 In the NALM6 leukemia mouse model, CD19-1XX CAR-T cells had shown superior anti-  
121 tumor activity than the CD19-WT cells.<sup>16</sup> In this study, we first investigated whether the CD19-  
122 1XX CAR-T cells controlled solid tumors better than the CD19-WT cells. With CRISPR/Cas9-  
123 mediated gene targeting,<sup>20</sup> we integrated CD19-WT or CD19-1XX CAR at the specific *TRAC*  
124 locus to generate CAR-T cells (Figure 1a, Figure S1a). The resulting CAR-T cells have similar  
125 knock-in efficiency (Figure 1b) and surface expression of CARs (Figure 1c). To have a direct  
126 comparison of the two CD19-specific CAR-T cells, we ectopically expressed the human CD19  
127 antigen in the pancreatic cell line Panc-1 for both the *in vitro* killing assay and the *in vivo* xenograft  
128 model (Figure S1b). With Panc-1<sup>CD19+</sup> cells as targets, CD19-1XX CAR-T cells displayed  
129 significantly lower cytotoxicity than CD19-WT cells at different E:T ratios in an 18h killing assay  
130 (Figure 1d, e), which was confirmed by results from two additional donors (Figure S1c, d). Data

131 summarized from three donors showed that 24h after antigen stimulation, CD19-1XX and CD19-  
132 WT CAR-T cells secreted similar amount of IL-2, IFN $\gamma$  and TNF $\alpha$  (Figure 1f, Figure S1e). In  
133 addition, our CFSE-based assay showed that 72h after antigen stimulation, the proliferation  
134 capacity of CD19-1XX was not statistically different from that of CD19-WT, though it had a  
135 higher trend (Figure 1g, h, Figure S1f). In summary, CD19-1XX cells displayed lower cytotoxicity,  
136 similar cytokine secretion and antigen-dependent proliferation *in vitro*.

137  
138 **CD19-1XX CAR-T cells showed better anti-tumor activity in a pancreatic tumor model**

139 We next compared the anti-tumor activity of two CD19 CAR-T cells in a xenograft  
140 pancreatic cancer model, where Panc-1<sup>CD19+</sup> cells were subcutaneously injected in the right flank  
141 of NSG mice (Figure 2a). We used a low dose of CAR-T cells ( $1 \times 10^6$ ) with similar transduction  
142 efficiency (Figure 1b) to better compare T cell potency in the CAR stress test.<sup>21</sup> Though both CAR-  
143 T cells inhibited initial tumor growth, mice injected with CD19-WT CAR-T cells started to relapse  
144 around day 29 while mice treated with CD19-1XX CAR-T cells relapsed around day 46 (Figure  
145 2b). At day 53, the average tumor volume of mice with CD19-1XX CAR-T cells was significantly  
146 smaller than that of mice injected with CD19-WT cells (Figure 2b, c). As CAR targeting *TRAC*  
147 locus knocked out the CD3 expression, we used antibodies against human CD4 or CD8 molecule  
148 to stain for human CAR-T cells in the tumor tissue. Our results revealed the existence of CD4<sup>+</sup>  
149 and CD8<sup>+</sup> T cells in the tissue even at day 53, albeit at a very low percentage (Figure 2d-f). Even  
150 though the percentage of either CD4<sup>+</sup> or CD8<sup>+</sup> T cells was not statistically different between CD19-  
151 1XX and CD19-WT groups, CD19-1XX groups had a trend of more CD4<sup>+</sup> and CD8<sup>+</sup> T cells  
152 (Figure 2e, f). In an independent *in vivo* experiment using CAR-T cells from a different donor  
153 (Figure S2a-c), we didn't observe differences in tumor growth, possibly because that donor was  
154 particularly potent, masking subtle differences. However, CD19-1XX group had more splenic total

155 CAR-T cells as well as more CD4<sup>+</sup> CAR-T cells than the CD19-WT group in mice 53 days after  
156 CAR-T infusion (Figure S2d; Figure 2g, h). Though no statistical difference, the CD19-1XX group  
157 displayed a lower percentage of PD-1<sup>+</sup>LAG-3<sup>+</sup> exhausted cells in both CD4<sup>+</sup> and CD8<sup>+</sup> populations  
158 (Figure S2e). Further phenotypic analysis of CAR-T cells demonstrated that the percentage and  
159 cell count of CD8<sup>+</sup> T<sub>EFF</sub> (CD45RA<sup>+</sup>CD62L<sup>-</sup>) were higher in CD19-1XX than CD19-WT (Figure  
160 2i, Figure S2f). For the CD4<sup>+</sup> population, CD19-1XX had a trend of more percentage of T<sub>CM</sub>  
161 (CD45RA<sup>-</sup>CD62L<sup>+</sup>), but less percentage of T<sub>EFF</sub> (Figure 2j, Figure S2g).

### 162 **1XX modification of AXL CAR enhanced its anti-tumor activity in a melanoma model**

163 After we confirmed that CD19-1XX cells were better than CD19-WT in both leukemia<sup>[16]</sup>  
164 and solid tumor models, we further investigated whether the 1XX design is also beneficial for  
165 CARs targeting antigens expressed naturally in solid tumors. AXL is a tyrosine kinase receptor,  
166 commonly overexpressed in both hematological malignancies and solid tumors.<sup>22</sup> Human  
167 melanoma cell line A375 was shown to have a high expression of AXL antigen (Figure S3a). We  
168 constructed a CAR targeting AXL (AXL-WT) using the scFv from an DAXL-88 antibody we  
169 reported before (Figure S3b), and also generated a 1XX-modified AXL-specific CAR for  
170 comparison (Figure 3a). Expression of AXL-WT and AXL-1XX CAR was also similar (Figure 3b,  
171 c). AXL-1XX induced lower killing of A375 cells than AXL-WT CAR-T cells (Figure 3d, e;  
172 Figure S3c, d). Meanwhile, data summarized from three donors suggested that AXL-1XX and  
173 AXL-WT CAR-T cells had similar cytokine secretion (Figure 3f, Figure S3e). The CFSE-based  
174 assay showed that AXL-1XX has stronger proliferative capability than AXL-WT upon antigen-  
175 stimulation (Figure 3g, h; Figure S3f).

176 Then we compared their anti-tumor activity in a xenograft melanoma model, where A375  
177 cells were subcutaneously injected in the right flank of NSG mice (Figure 4a). Interestingly, AXL-

178 WT CAR-T failed to control tumor growth when injected at a low  $1 \times 10^6$  dose while AXL-1XX  
179 CAR-T cells significantly reduced tumor size at the same dose (Figure 4b-e). We confirmed this  
180 finding in an independent experiment with CAR-T cells produced from a different donor (Figure  
181 S4a-d). Our results revealed the existence of CD4<sup>+</sup> and CD8<sup>+</sup> T cells in the tissue at day 14 (Figure  
182 4e). The percentage of CD4<sup>+</sup> T cells was not statistically different between the AXL-1XX and  
183 AXL-WT groups, while the AXL-1XX groups had more percentage of CD8<sup>+</sup> T cells (Figure 4f,  
184 g). The analysis of CAR-T cells extracted from mice revealed that the total number of the AXL-  
185 1XX CAR-T cells was about 110 fold more than that of the AXL-WT cells (Figure S4e). The  
186 dramatic increase of cell numbers from AXL-1XX CAR-T cells were seen in both CD4<sup>+</sup> (116 fold)  
187 and CD8<sup>+</sup> populations (121 fold) (Figure 4h, i). Further phenotypic analysis showed that AXL-  
188 1XX CAR-T cells had a significantly higher percentage of central memory cells and lower  
189 percentage of effector cells in both CD4<sup>+</sup> and CD8<sup>+</sup> populations (Figure 4j, k). As the total CAR-  
190 T cells were much higher in 1XX, the total numbers of central memory cells and effector cells  
191 were both higher in mice injected with AXL-1XX cells (Figure S4g, h). Meanwhile, 1XX led to  
192 the trend of fewer percentage of PD-1<sup>+</sup>LAG3<sup>+</sup> exhausted cells than AXL-WT cells (Figure S4f).  
193 To summarize, the comparison of AXL-1XX and AXL-WT was mostly consistent with the CD19-  
194 1XX and CD19-WT comparison. Although the 1XX design reduced CAR-T cytotoxicity *in vitro*,  
195 it enhanced the anti-tumor activity of CARs targeting two solid tumor models *in vivo*, which has  
196 more significance for CAR-T therapy.

### 197 **1XX CAR induced higher Ca<sup>2+</sup> level and faster Erk activation than WT CAR**

198 Our previous work with the leukemia model indicated that CD19-1XX cells had a better  
199 anti-tumor activity because they were more persistent and comprised of increased numbers of  
200 memory cells.<sup>16</sup> It is intriguing how a simple 1XX calibration can have a profound impact on

201 cellular phenotypes and functions. To complement the global RNAseq comparison between CD19-  
202 1XX and CD19-WT,<sup>16</sup> we next compared CAR-mediated signaling dynamics in CD19-1XX and  
203 CD19-WT cells with different FRET biosensors. FRET biosensors enable monitoring of the  
204 molecular activity at a single cell level with high spatiotemporal resolution. Here, all the FRET  
205 changes of the biosensor in every cell was normalized to its unstimulated baseline level so we  
206 could directly compare antigen-induced activation.

207         As ZAP70 kinase directly binds phosphorylated ITAMs of TCR and CARs to get activated,  
208 the 1XX mutation might directly affect the activity of ZAP70. Using a recently developed ZAP70  
209 FRET biosensor with improved dynamic range, ZAP70 activation dynamics can be observed in  
210 CAR-T cells upon antigen stimulation.<sup>17</sup> We expressed this biosensor together with either CD19-  
211 1XX or CD19-WT CAR, and performed live cell FRET imaging (Figure S5a). ZAP70 activation  
212 can be observed by the FRET biosensor after CAR-antigen interaction. The activation dynamics  
213 induced by CD19-1XX and CD19-WT CAR were not statistically different (Figure 5a-e, Figure  
214 S5b, c). However, CD19-1XX exhibited a trend of lower ZAP70 activity within the first 5min but  
215 eventually caught up with CD19-WT at 30mins. We next investigated cytosolic Ca<sup>2+</sup> elevation<sup>18</sup>  
216 and Erk activation, as they are key signaling events downstream of both TCR/CD3 $\zeta$ -ZAP70 and  
217 CD28-PI3K pathways and have profound effects on T cell functions through transcriptional  
218 regulation. Our results showed that Ca<sup>2+</sup> elevation at 1.5min in 1XX cells was significantly higher  
219 than that in WT cells (Figure 5f-j, Figure S5d, e). Moreover, analysis of CAR-T cells transduced  
220 with Erk biosensors<sup>19</sup> revealed that CD19-1XX directed faster Erk activation than CD19-WT did  
221 upon target cell binding (Figure 5k-o, Figure S5f, g). We further analyzed the Shp1 recruitment  
222 and Lck activation in CAR-T cells. Our co-IP results showed that even though there was no  
223 significant difference of recruited Shp1 after antigen stimulation between WT and 1XX CAR, the

224 baseline CAR-associated Shp1 (Time 0) was lower in 1XX CAR group (Figure S6). With a FRET-  
225 based Lck biosensor to monitor Lck activity,<sup>23</sup> we showed that WT and 1XX induced little Lck  
226 activation upon antigen recognition and there was no statistical difference between these two  
227 groups (Figure S7). Thus, even though 1XX-induced a trend of reduced ZAP70 activity, it  
228 increased antigen-dependent Ca<sup>2+</sup> elevation and sped up Erk activation, which were correlated  
229 with higher therapeutic potency.

## 230 Discussion

231 1XX design has been shown to be advantageous in the CD19 CAR context against  
232 leukemia. The most relevant translational question is whether 1XX modification is also beneficial  
233 against solid tumors. Though a prior study reported the 1XX design of a mesothelin-targeting CAR  
234 was effective in a pleural mesothelioma mouse model,<sup>24</sup> there was no direct comparison with its  
235 WT counterpart and the underlying molecular mechanisms were not investigated. Our study  
236 demonstrated that 1XX modification can enhance CAR-T cell efficacy against solid tumors in two  
237 different CAR settings and tumor models, suggesting this could be a general optimization strategy.  
238 The increased efficacy was attributed to the observations that CD19-1XX CAR-T cells extracted  
239 from leukemic mice were of higher number and had a higher percentage of CD62<sup>+</sup>CD45RA<sup>-</sup> T<sub>CM</sub>  
240 cells than CD19-WT cells.<sup>16</sup> In our study, we tried to isolate CAR-T cells from subcutaneous  
241 tumors to analyze their phenotype but we could not detect enough CAR-T cells (data not shown).  
242 This was most likely because we injected a low CAR-T cell dose and collected the tumor tissue at  
243 the very last time point. We chose a low CAR-T cell dose as a “stress test” for better comparison  
244 of T cells with different CAR constructs.<sup>21</sup> The low number of CAR-T cells in tumors was  
245 corroborated by in situ immunostaining of CAR-T cells. Quantitative analysis of immunostaining  
246 indicated a trend of more CD19-1XX cells than CD19-WT cells, which was consistent with the

247 results from the leukemic mouse model. Nevertheless, we could isolate enough CAR-T cells from  
248 the mouse spleen instead of tumors for detailed characterization. The 1XX mutation in AXL-CAR  
249 increased the number of total CAR-T cells by 110.5 fold, and these cells displayed an increased  
250 central memory phenotype and decreased exhaustion trend, which was consistent with the effect  
251 of 1XX modification on CD19 CAR.

252 1XX CAR-T cells have significantly lower cytotoxicity than WT CAR-T cells when killing  
253 Panc-1<sup>CD19+</sup> cells. Previous data showed that CD19-1XX and CD19-WT CAR-T cells display  
254 similar cytotoxicity against leukemic NALM6 cells *in vitro*.<sup>16</sup> AXL-specific 1XX CAR-T cells  
255 also have decreased killing against A375 tumor cells. Thus it is possible that results of *in vitro*  
256 killing assays cannot predict *in vivo* anti-tumor activities of different CAR-T cells. Here, the 1XX  
257 design has already been combined with the TRAC-targeting of CAR to take advantage of two  
258 optimization methods.<sup>20</sup> Whether 1XX can be combined with other known therapeutic  
259 enhancement strategies, such as IL-12, PD-1 blocking scFv or IL-7/CCL19, to further enhance  
260 CAR-T performance against solid tumors, warrants further investigation.

261 RNAseq analysis of CD19-1XX and CD19-WT cells revealed their global transcriptional  
262 difference 24h after target recognition,<sup>16</sup> but how 1XX mutation leads to differential gene  
263 expression was still elusive. Here we employed different FRET biosensors to probe the signaling  
264 dynamics of three key molecules downstream CAR activation (Figure 6). Each ITAM from CD3 $\zeta$   
265 has two tyrosines, both of which need to be phosphorylated to recruit ZAP70 so that ZAP70 can  
266 be phosphorylated by Lck.<sup>10</sup> But singly-phosphorylated ITAMs was shown to instead recruit Shp1  
267 phosphatase, which in turn inhibits Lck activity through negative feedback<sup>25</sup> (Figure 6). Indeed,  
268 before antigen stimulation CAR-associated Shp1 level was lower in 1XX CAR-T cells than that  
269 in WT cells (Figure S6a, b). Additional results assayed with FRET-based Lck biosensor showed

270 no statistical difference of induced Lck activation by 1XX and WT CARs (Figure S7a, b), which  
271 didn't exclude the possibility of enhanced Lck activity by 1XX CAR as the limited dynamic range  
272 of the Lck biosensor may mask the subtle difference in signaling dynamics.<sup>23</sup> Thus, 1XX with  
273 reduced ITAMs could possibly enhance Lck activity by decreasing the amount of singly-  
274 phosphorylated ITAMs and associated Shp1. The total ZAP70 activity of 1XX would be the net  
275 result of these two opposing effects, as reduced ITAM numbers decreased the amount of bound  
276 ZAP70, but increased the activation of bound ZAP70 by enhanced Lck activity. Our FRET data  
277 showed that even though ZAP70 activity in 1XX was not statistically different from that in WT,  
278 the trend was lower (Figure 5e).

279         If only the CD3 $\zeta$ -ZAP70 pathway was considered, the 1XX mutation should not alter the  
280 Ca<sup>2+</sup> and Erk activation through LAT. But in the context of CD28-based second generation CAR,  
281 CD28 cytosolic domain after being phosphorylated by Lck can also augment Ca<sup>2+</sup> and Erk  
282 signaling through PI3K activation<sup>12,13</sup> (Figure 6). As 1XX can enhance Lck activity through  
283 reduced singly-phosphorylated ITAMs and associated Shp1,<sup>26,27</sup> CD28 phosphorylation by Lck in  
284 1XX CAR may be strengthened, which promotes higher or faster PI3K activation<sup>12,13</sup> (Figure 6).  
285 Our FRET-based imaging revealed that 1XX resulted in significantly higher Ca<sup>2+</sup> elevation and  
286 more rapid Erk activation than WT upon antigen binding (Figure 5), which was consistent with  
287 the prediction from a mathematical model.<sup>25</sup> Increased Ca<sup>2+</sup> would bind to calcineurin and activate  
288 transcription factors of the NFAT family to regulate cytokine gene expression and other genes  
289 critical for the T cell functions.<sup>28,29</sup> Erk could further activate transcription factors, such as Elk-1  
290 and AP-1.<sup>30,31</sup> Particularly, the Erk pathway was shown to be pivotal for both human memory Th17  
291 cells and CD8 T cell differentiation,<sup>32-34</sup> suggesting that faster Erk activation kinetics of 1XX may  
292 be linked to CAR-T cell differentiation. Feucht et al.<sup>16</sup> compared the function of three CARs with

293 decreasing activation strength, WT, 1XX and XX3. 1XX resulted in the highest number of memory  
294 cells and XX3 CAR-T group had the least number of exhausted cells. Liu et al. showed that XX3  
295 had much weaker ZAP70 activity than WT CAR upon antigen stimulation while they had similar  
296 Erk activity.<sup>17</sup> However, our data demonstrated that 1XX CAR had higher Erk activity than WT  
297 CAR while they had similar ZAP70 activity. Taken together, we speculate that the ZAP70  
298 activation seems to be related to the exhaustion phenotype while the Erk activation seems to be  
299 related to the memory phenotype. Further investigation are needed to depict the relationship  
300 between signal strength and T-cell phenotypes.

301 Our study established the superior anti-tumor effect of 1XX CAR in two preclinical solid  
302 tumor models and revealed the delicate changes of signaling dynamics caused by 1XX CAR,  
303 paving the way for the clinical translation of 1XX CAR in treating solid tumors.

## 304 **Materials and methods**

### 305 **Cells lines and culture conditions**

306 Panc-1 cells were transduced to express human CD19 as described previously,<sup>21,35</sup> Panc-1<sup>CD19+</sup>  
307 cells were sorted by Flow Cytometry. Panc-1<sup>CD19+</sup>, A375 cells were transduced to express firefly  
308 luciferase, and (FFLuc)-2A-green fluorescent protein (GFP), and GFP<sup>+</sup> cells were sorted by Flow  
309 Cytometry. Panc-1, A375, 293T and NIH/3T3 were cultured in Dulbecco's modified Eagle  
310 medium (DMEM, Gibco), with 10% FBS (Vistech) and 1% penicillin/streptomycin (Gibco).  
311 Jurkat cells were cultured in a RPMI-1640 medium (Gibco) with 10% FBS and 1%  
312 penicillin/streptomycin.

### 313 **RNP production**

314 RNPs were produced by complexing gRNA and Cas9 protein. Modified guide RNAs (gRNAs)  
315 was synthesized by GeneScript. Guide RNAs were reconstituted at 1 $\mu$ g/ $\mu$ L in RNase free water,

316 Cas9 proteins were produced by our lab as described in our previous work,<sup>36</sup> In brief, they were  
317 complexed in 2:1 gRNA to Cas9 molar ratio at room temperature for 20 min then electroporated  
318 into T cells immediately after complexing.<sup>36</sup>

### 319 **Plasmid construction**

320 Based on pAAV-TRAC-1928z plasmid (as described in our previous work,<sup>36</sup> named as CD19-  
321 WT), we designed and cloned the pAAV-TRAC-1928z-1XX (named as CD19-1XX). Briefly, the  
322 CD19 CAR comprises a single chain variable fragment<sup>20</sup> scFv specific for the human CD19 (AXL  
323 CAR comprises a single chain variable fragment of anti-AXL<sup>37</sup> specific binding to human AXL),  
324 preceded by a CD8a leader peptide and followed by CD28 hinge, transmembrane and intracellular  
325 regions and CD3 $\zeta$  intracellular domain. The CAR cDNA is followed by the bovine growth  
326 hormone polyA signal (bGHpA). In brief, pAAV-TRAC-AXL28z/1XX plasmids were  
327 constructed with the following primers. AAV-AXL-forward primer:  
328 GTGGAGGAGAATCCCGGCCCCatggctctcccagtgactgcctactg; AAV-AXL-reverse primer:  
329 GCAACTAGAAGGCACAGTCGcctagggatttagcgagggggcagggcctg, the anti-AXL scFv fragment  
330 was obtained by PCR and inserted into pAAV-TRAC-1928z-WT or pAAV-TRAC-1928z-1XX  
331 plasmid which was digested out as 1928z-WT or 1928z-1XX fragments by NcoI/AvrII,  
332 respectively. The pAAV-TRAC-AXL28z/1XX plasmids were prepared using standard molecular  
333 biology techniques as described previously.<sup>16</sup> The Lenti-ZAP70-BS-CD19 CAR, Lenti-Ca<sup>2+</sup>-BS-  
334 CD19 CAR and Lenti-Erk-BS-CD19 CAR plasmids were constructed as in our previous work<sup>17</sup>  
335 for FRET analysis. Lenti-Lck-BS-CD19 CAR plasmids were constructed as in previous work.<sup>23</sup>

### 336 **Isolation and expansion of human T cells**

337 Human PBMCs were isolated from the peripheral blood of healthy volunteers. Ethical permission  
338 was granted by the School of Medicine, Zhejiang University. All blood samples were handled

339 following the required ethical and safety procedures. Peripheral blood mononuclear cells were  
340 isolated by ficoll density gradient centrifugation (Dakewe) and T cells were purified using the Pan  
341 T Cell Isolation Kit (Miltenyi Biotec), and stimulated with CD3/CD28 T cell Activator Dynabeads  
342 (Thermofisher) as described previously,<sup>20</sup> then cultured in X-VIVO 15 Serum-free Hematopoietic  
343 Cell Medium (Lonza), which was supplemented with 10% fetal bovine serum (Vistech), 5ng/mL  
344 IL7 (interleukin-7) and 5ng/ml IL15 (interleukin-15) (Novoprotein) for the experiments. The  
345 medium was changed every 2 days, and cells were plated at  $10^6$  cells/mL. After stimulated for 48  
346 h, human T cells were debeaded for gene targeting experiments.

### 347 **CAR-T cell production**

348 RNPs were electroporated into T cells 2 days after CD3/CD28 bead stimulation. Before  
349 electroporation, debeaded T cells were resuspended in X-VIVO 15 medium. For each reaction,  
350  $3 \times 10^6$  cells were mixed with 3.6  $\mu$ L (80 pmol) RNPs in a total volume of 120  $\mu$ L and transferred  
351 to a 120ul cuvette and electroporated with an Cell Electroporator (CELETRIX). Thirty minutes  
352 later, the AAV virus (MOI= $1 \times 10^5$ ) (Vigene Biosciences, China) was added. Following  
353 electroporation, cells were immediately transferred into the culture medium (X-VIVO 15 with 10%  
354 FBS and 1% penicillin/streptomycin). Two hours later, IL-7 (5 ng/mL) and IL-15 (5 ng/mL) were  
355 added. Then the medium was changed every 48 h. Seven days after electroporation, cells were  
356 harvested for fluorescence-activated cell sorting (FACS) analysis to determine the knock-in  
357 efficiency in each condition.

### 358 **Flow cytometry**

359 The following fluorophore-conjugated antibodies were used. For CD19 CAR staining, an Alexa  
360 Fluor 647 AffiniPure F(ab')<sub>2</sub> Fragment Goat Anti-Mouse IgG was used (Jackson  
361 ImmunoResearch); for AXL CAR staining, an Alexa Fluor 647 AffiniPure anti-HA tag Goat Anti-

362 Mouse IgG was used (BD Bioscience). A375 stained with anti-AXL PE-conjugated antibodies  
363 (FAB154P, R&D); and the DAXL-88 (anti-AXL) binding assay used Alexa Fluor 647 AffiniPure  
364 anti-Fc tag Goat Anti-Human IgG (410711, BioLegend). Anti-Human CD4 antibody (BD, Horizon,  
365 BUV395), anti-Human CD8 antibody (BD, Pharmin, APC-CY<sup>TM</sup>7), anti-Human CD279(PD-1)  
366 antibody (Invitrogen, eBioscience, PE-Cyanine7), anti-Human CD223(LAG-3) antibody  
367 (Invitrogen, eBioscience, Percp-eFluor<sup>TM</sup>710), anti-Human CD45RA antibody (Invitrogen,  
368 eBioscience, FITC), anti-Human CD62L antibody (Invitrogen, eBioscience, eFluor450). For cell  
369 counting, CountBright Absolute Counting Beads were added (Invitrogen) according to the  
370 manufacturer's instructions. For *in vivo* experiments, Fc receptors were blocked using FcR  
371 Blocking Reagent, mouse (Miltenyi Biotec). CytoFLEX (Beckman) was used with FlowJo 7.6  
372 software for analysis. All FACS plots presenting CAR-T cell phenotype data were conducted on  
373 gated APC positive CAR-T cells. For Co-immunoprecipitation assay, anti-HA magnetic beads  
374 (MCE, HY-K020) were used according to the manufacturer's instructions. For western blot assay,  
375 anti-HA (Cell Signaling Technology, 3724S), anti-Shp1 (Cell Signaling Technology, 3759S) and  
376 anti-GAPDH (Cell Signaling Technology, 5174S) were 1:1000 dilution, horseradish peroxidase  
377 conjugated secondary Abs (Goat-anti-Rabbit from Thermo Scientific) was 1:5000 dilution.

#### 378 **Antigen stimulation and cytokines analysis assay**

379 Nine days after gene targeting, the CAR-T cells and irradiated target cells NIH/3T3<sup>CD19+</sup> or A375  
380 were cocultured at an E:T ratio of 4:1 without the addition of exogenous cytokines for 24 h, then  
381 cell culture supernatants were harvested and analyzed using a BD Cytometric Bead Array (CBA)  
382 Human Soluble Protein Master Buffer Kit (BD Biosciences) according to the manufacturer's  
383 instructions. The detection reagent is a mixture of phycoerythrin (PE)-conjugated antibodies,  
384 which provides a fluorescent signal in proportion to the amount of bound analyte. Soluble cytokine

385 can be measured using flow cytometry to identify particles with fluorescence characteristics of  
386 both the bead and the detector.

### 387 **Proliferation assay**

388 For the proliferation assay, CAR-T cells were labeled with Carboxyfluorescein diacetate  
389 succinimidyl ester (CFSE) using a kit from Beyotime. Briefly, cells were resuspended in RPMI  
390 1640 with 10% FBS at a final concentration of  $5 \times 10^6$  cells/mL, and CFSE solution was added at  
391 the suggested working concentration. The CAR-T cells were incubated at 37 °C for 10 min, and  
392 then washed three times with RPMI 1640 with 10% FBS. CFSE-labeled cells were further plated  
393 in 24-well plates, co-cultured with irradiated 3T3<sup>CD19+</sup> or A375 cells (E:T=4:1) for 72 h.  
394 Unstimulated but CFSE-labeled CAR-T cells served as the control. 72h later CAR-T cells stained  
395 with CFSE were analyzed by CytoFLEX (Beckman) with FlowJo 7.6 software.

### 396 **Cytotoxicity assay**

397 Nine days after gene targeting, CAR-T cells were collected for luciferase-based cytotoxicity assay  
398 using FFluc-GFP Panc-1<sup>CD19+</sup> or A375 as target cells. The target (T) and effector (E) cells were  
399 co-cultured in triplicates at indicated E/T ratios using black 96-well flat plates with  $2.5 \times 10^4$  target  
400 cells in a total volume of 100  $\mu$ L per well in X-vivo 15 medium. Target cells alone were plated at  
401 the same cell density to determine the maximal luciferase expression (relative light units (RLU));  
402 18 h later, 100  $\mu$ L luciferase substrate (Goldbio) was directly added to each well. Emitted light  
403 was detected in a luminescence plate reader. Lysis percentage was determined as  
404  $(1 - (RLU_{\text{sample}}) / (RLU_{\text{max}})) \times 100$ .

### 405 **Immunofluorescence of tumor tissues**

406 The mice were euthanized by carbon dioxide (CO<sub>2</sub>) inhalation, and the tumors were harvested and  
407 fixed in 4% paraformaldehyde. Tumor tissue were sectioned for anti-CD4 (GB13064-1, Servicebio)

408 and anti-CD8 (GB13068, Servicebio) staining. All procedures followed the manufacturer's  
409 protocol. In brief, tumor tissue slides were incubated at 65°C for 1h, blocked with PBS containing  
410 3% BSA for 30 min at room temperature, and then incubated with the primary antibody at 4°C  
411 overnight. The secondary antibody was incubated at room temperature for 50 min in dark  
412 conditions. Then slides were incubated with DAPI solution at room temperature for 10 min in dark  
413 conditions. Images were acquired by fluorescent microscopy. The nucleus is blue by labeling with  
414 DAPI. Positive cells are green or red according to the fluorescent labels used.

#### 415 **Co-immunoprecipitation assay**

416 Briefly,  $2 \times 10^6$  CD19-WT or CD19-1XX CAR-expressing Jurkat cells were mixed with  $1 \times 10^6$   
417  $3T3^{CD19+}$  cells at room temperature. After the co-culture, the cells were resuspended in lysis  
418 buffer<sup>38</sup> on ice for 30 min, and centrifuged at 14000 g for 30 min to remove insoluble materials.  
419 The soluble cell lysate was mixed with anti-HA-beads and incubated for 3 h at 4°C to  
420 immunoprecipitate HA-tagged CARs. After rinsed with wash buffer,<sup>38</sup> the immunoprecipitated  
421 proteins were eluted with SDS sample buffer, subjected to SDS-PAGE, and immunoblotted with  
422 the indicated antibodies.

#### 423 **Western Blot assay**

424 The protein lysate was normalized according to the amount of CAR expression and resolved on 4%  
425 - 15% SDS polyacrylamide gel electrophoresis gels (SDS-PAGE, Bio-Rad). After protein transfer  
426 onto Polyvinylidene fluoride membranes (Bio-Rad), membranes were blocked in 5% bovine  
427 albumin in TBS-T and incubated with primary and secondary Abs in TBS-T with 2% bovine  
428 albumin. The following Abs were used:  $\alpha$ -SHP1,  $\alpha$ -HA tag and  $\alpha$ -GAPDH (all from Cell Signaling  
429 Technology), horseradish peroxidase conjugated secondary Abs (Goat-anti-Rabbit from Thermo  
430 Scientific). Then the membrane was incubated with the primary antibody at 4°C overnight,

431 followed by incubation with the secondary antibody at room temperature for 1 hour. Lastly, the  
432 membrane was visualized with standard chemiluminescence.

### 433 **Live cell imaging with FRET-based biosensors**

434 The CD19 CAR-T cells expressing biosensors were generated by the lentivirus transduction of the  
435 Jurkat T cells.<sup>17</sup> For imaging of CAR signaling upon antigen stimulation, CAR-T cells were  
436 dropped on the glass-bottom dishes that have been coated with the NIH-3T3 cells expressing CD19  
437 antigens. The time-lapse fluorescence images were taken with a Nikon Eclipse Ti inverted  
438 microscope at an interval of 30 s. The W-VIEW GEMINI imaging splitting optics (Hamamatsu,  
439 Japan) with an iXon Ultra 897 camera was used to capture the ECFP (a 474/40 nm emission filter)  
440 and FRET (a 535/25 nm emission filter) fluorescent signals simultaneously. During imaging, the  
441 cells were maintained with 5% CO<sub>2</sub> at 37 °C using the Tokai Hit ST Series Stage Top Incubator  
442 (Tokai Hit, Japan).

### 443 **Mouse systemic tumor model**

444 Six to eight week old NOD/SCID/IL-2R $\gamma$  null (NSG) mice (Shanghai Jihui, China) were used. All  
445 mice were housed at the Westlake University under pathogen-free conditions, and all procedures  
446 were approved by the ethical committee of Westlake University. Mice were subcutaneously (s.c.)  
447 injected a total of  $1 \times 10^6$  target tumor cells (Panc-1<sup>CD19+</sup> or A375) into the right flanks. Seven days  
448 later  $1 \times 10^6$  CD19-specific or  $2.5 \times 10^6$  AXL-specific CAR-T cells were injected. Tumor size was  
449 recorded every 3-4 days using a vernier caliper. Tumor volume was calculated as follows: tumor  
450 volume = long diameter  $\times$  (short diameter<sup>2</sup>)/2. NSG mice were euthanized when the tumor size  
451 exceeded 14mm (Panc-1<sup>CD19+</sup> model) or 19mm (A375 model), so Panc-1<sup>CD19+</sup> model mice were  
452 euthanized and the tissue was harvested 53 days after CAR-T cell injection. A375 model mice  
453 were euthanized and the tissue was harvested 26 days after CAR-T cell injection. For each group,

454 3-5 individual mice were included. Stratified randomization based on the initial tumor size was  
455 used. No animal data were excluded in this study. No strategy was used to minimize potential  
456 confounders. D.Y and J.C. were aware of the group allocation at the different stages of the  
457 experiment.

#### 458 **Statistical analysis**

459 Unpaired Student *t* tests or one-way ANOVA (with the appropriate multiple comparisons test) was  
460 carried out using the GraphPad Prism version 7.0 (GraphPad Software Inc). ns,  $P > 0.05$ ; \*,  $P <$   
461  $0.05$ ; \*\*,  $P < 0.01$ ; \*\*\*,  $P < 0.001$  and \*\*\*\*,  $P < 0.0001$ .

#### 462 **Abbreviations**

463 ITAMs: Immunoreceptor tyrosine-based activation motifs; CAR-T: Chimeric antigen receptor  
464 engineered T cells; WT: Wild type; CFSE: Carboxyfluorescein diacetate succinimidyl ester; IFN:  
465 Interferon; IL: Interleukin; TNF: Tumor necrosis factor; FRET: Fluorescence resonance energy  
466 transfer; Co-IP: Co-Immunoprecipitation; WB: Western Blot; IB: Immunoblot; Lck: leukocyte-  
467 specific protein tyrosine kinase; SHP1: Src-Homology 2 domain Phosphatase-1; ZAP70: 70-kDa  
468 zeta-associated protein;  $Ca^{2+}$ : Calcium; Erk: Extracellular-regulated protein kinases; FBS: Fetal  
469 bovine serum; DMEM: Dulbecco's Modified Eagle Medium; RPMI: Roswell Park Memorial  
470 Institute, DAG: Diacylglycerol; IP3: Inositol 1,4,5-trisphosphate; PIP3: Phosphatidylinositol  
471 3,4,5-trisphosphate.

#### 472 **Acknowledgment**

473 This research was funded by the National Key R&D Program of China 2021YFA0909900 (J.S.),  
474 the National Natural Science Foundation of China grants 31971324 (J.S.), 82161138028 (J.S.),  
475 81973993 (X.G.), Zhejiang Provincial Natural Science Foundation grant LR20H160003 (J.S.),  
476 LR20C070001 (X.G.) and the Leading Innovative and Entrepreneur Team Introduction Program

477 of Zhejiang grant 2020R01006 (J.S.). The authors thank the support of Zhejiang Provincial Key  
478 Laboratory of Immunity and Inflammatory diseases and Zhejiang University School of Medicine  
479 core facilities. We also thank Courtney R. Kwong for editing the manuscript.

#### 480 **Authors' contributions**

481 Y.D. and J.S. designed the studies and conceived the experiments. Y.D., J.C. and X.M. performed  
482 most of the experiments; L.L., K.S., X.W., Y.W., Z.H. and H.L. conducted data analysis; Y.D. and  
483 J.S. wrote the manuscript. Y.H., C.Z., X.G. and Y.W. discussed the manuscript, X.G., J.S. were  
484 responsible for funding acquisition. All authors read and approved the final manuscript.

#### 485 **Declaration of interests**

486 A patent application related to this study on which J.S. is named as an inventor has been approved.  
487 The other authors declare no competing interests.

600 Figure legends

601 Figure 1. CD19-1XX CAR-T cells show reduced cytotoxicity but enhanced proliferation *in vitro*.

602 (a) Targeting of CD19-WT or CD19-1XX CAR into the *TRAC* locus by CRISPR/Cas9. (b) FACS  
603 analysis showing the expression levels of two CD19 CARs. Data are representative of at least three  
604 independent experiments with similar results. Untransduced T cells were used as the control. (c)  
605 Normalized CD19-WT and CD19-1XX CAR expression (n=3, for each donor, MFI value of 1XX  
606 CAR was normalized to MFI of WT CAR). (d) Cytotoxic activity of CD19-WT and CD19-1XX  
607 CAR-T cells using an 18 h bioluminescence assay with FFL-expressing Panc-1<sup>CD19+</sup> cells as targets.  
608 (n=3, 1 experiment performed in triplicates from 1 donor). (e) Normalized lysis of target cells by  
609 CD19-WT or CD19-1XX CAR-T cells at E:T=1:1 (n=9, 3 independent experiments performed in  
610 triplicates from 3 donors). (f) Normalized cytokine secretion of CD19-WT and CD19-1XX cells  
611 were detected after stimulation by target cells. (E:T=4:1, n=9, 3 independent experiments  
612 performed in triplicates from 3 donors). For each donor, cytokine secretion by 1XX CAR was  
613 normalized to that secreted by WT CAR. (g) The proliferation of CD19-WT and CD19-1XX CAR-  
614 T cells analyzed by CFSE assay. Unstim represents CAR-T cells without 3T3<sup>CD19+</sup> cell coculture  
615 and stim represents CAR-T cells stimulated with 3T3<sup>CD19+</sup> cells for 72h. (E:T=4:1, n=3, 1  
616 experiment performed in triplicates from 1 donor). (h) CAR-T cell antigen-dependent proliferation  
617 fold calculated by stim/unstim ratio (E:T=4:1, n=9, 3 experiment performed in triplicates from 3  
618 donors). All data are mean ± SD.

619

620 Figure 2. CD19-1XX CAR-T cells show better anti-tumor activity in a pancreatic tumor model *in*  
621 *vivo*.

622 (a) Timeline of CD19 CAR-T treatment in the mouse model. (b) Panc-1<sup>CD19+</sup> -bearing mice were  
623 treated with  $1 \times 10^6$  CD19 CAR-T cells as indicated, and the tumor burden (tumor volume) of mice

624 was measured at indicated days (n=4 mice each group). For mouse experiments, Control used PBS.  
625 (c) Tumor tissue from mice treated with indicated CAR-T cells. (d) Tumor tissue from mice treated  
626 with indicated CAR-T cells was sliced and stained with antibodies against human CD4 and CD8  
627 (n=4). The percentage of CD4<sup>+</sup> (e) and CD8<sup>+</sup> (f) T cells in tumor tissue from different groups of  
628 mice (n=4). Number of CD4<sup>+</sup> CAR-T cells (g), CD8<sup>+</sup> CAR-T cells (h) in the spleen of mice 53  
629 days post CAR-T infusion (n=5). (i, j) Phenotype of CAR-T cells in the spleen of mice 53 days  
630 after CAR-T infusion as demonstrated by the percentage of T<sub>CM</sub> (CD45RA<sup>-</sup>CD62L<sup>+</sup>) and T<sub>EFF</sub>  
631 (CD45RA<sup>+</sup>CD62L<sup>-</sup>) cells (n=5). All data are mean ± SD.

632

633 Figure 3. 1XX modification of AXL CAR reduced cytotoxicity but enhanced proliferation *in vitro*.

634 (a) Targeting of AXL-WT or AXL-1XX into the *TRAC* locus by CRISPR/Cas9. (b) FACS analysis  
635 showing the expression levels of two AXL CARs. Data are representative of at least three  
636 independent experiments with similar results. Untransduced T cells were used as the control. (c)  
637 Normalized CD19 WT and 1XX CAR expression (n=3, for each donor, MFI value of 1XX CAR  
638 was normalized to MFI of WT CAR). (d) Cytotoxic activity of AXL-WT and AXL- 1XX using an  
639 18 h bioluminescence assay with FFL-expressing A375 cells as targets. (n=3, 1 experiment  
640 performed in triplicates from 1 donor). (e) Normalized lysis of target cells by AXL-WT or AXL-  
641 1XX CAR-T cells at E:T=1:1 (n=9, 3 independent experiments performed in triplicates from 3  
642 donors). (f) Normalized cytokine secretion of AXL-WT and AXL-1XX were detected 24h after  
643 stimulation by target cells (E:T=4:1, n=9, 3 independent experiments performed in triplicates from  
644 3 donors). For each donor, cytokine secretion by 1XX CAR was normalized to that secreted by  
645 WT CAR. (g) The proliferation of AXL-WT and AXL-1XX CAR-T cells analyzed by CFSE assay.  
646 Unstim represents CAR-T cells without target cell coculture and Stim represents CAR-T cells  
647 stimulated with target cells for 72h. (E:T=4:1, n=3, 1 experiment performed in triplicates from 1

648 donor). (h) CAR-T cell antigen-dependent proliferation fold calculated by Stim/Unstim ratio  
649 (E:T=4:1, n=9, 3 experiment performed in triplicates from 3 donors). All data are mean  $\pm$  SD.

650

651 Figure 4. 1XX modification of the AXL CAR enhance its anti-tumor activity in a melanoma tumor  
652 model.

653 (a) Timeline of of the AXL CAR-T treatment in the mouse model. (b) A375-bearing mice were  
654 treated with  $2.5 \times 10^6$  AXL CAR-T cells and the tumor burden (tumor volume) of mice were  
655 measured at the indicated days (n=4, 5, 5 mice in respective groups). Control, PBS. (c) Tumor  
656 tissue of the mice treated with indicated CAR-T cells (n=4, 5, 5). (d) The weight of the tumors  
657 from different groups of mice (n=4, 5, 5). (e) Tumor tissue from the mice treated with indicated  
658 CAR-T cells was sliced and stained with antibodies against human CD4 and CD8 (n=5). The  
659 percentage of CD4<sup>+</sup> (f) and CD8<sup>+</sup> (g) T cells in tumor tissue from the different groups of mice  
660 (n=5). The number of CD4<sup>+</sup> CAR-T cells (h) and CD8<sup>+</sup> CAR-T cells (i) in the spleen of mice 26  
661 days post CAR-T infusion (n=5, 3). (j, k). The phenotype of CAR-T cells in the spleen of mice 26  
662 days after CAR-T infusion as demonstrated by the percentage of T<sub>CM</sub> (CD45RA<sup>-</sup>CD62L<sup>+</sup>) and T<sub>EFF</sub>  
663 (CD45RA<sup>+</sup>CD62L<sup>-</sup>) cells (n=5, 3). All data are mean  $\pm$  SD.

664

665 Figure 5. CAR-mediated signaling dynamics in 1XX and WT CAR-T cells revealed by FRET  
666 biosensors.

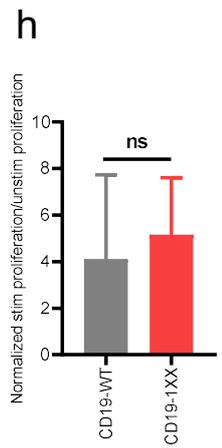

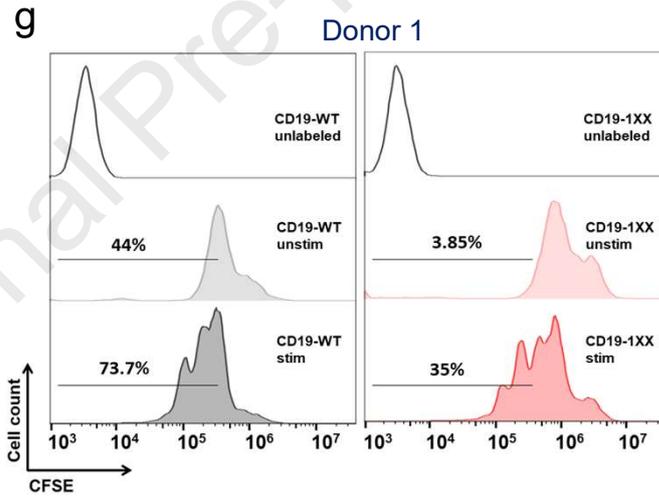

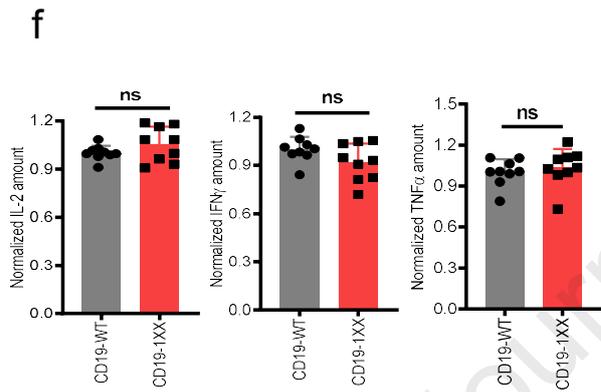

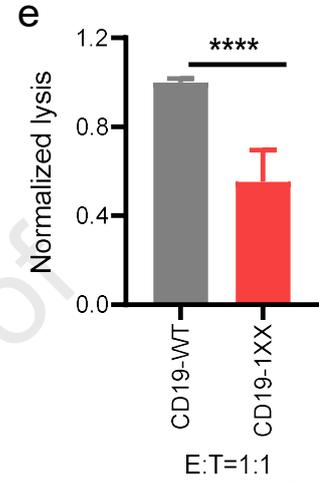

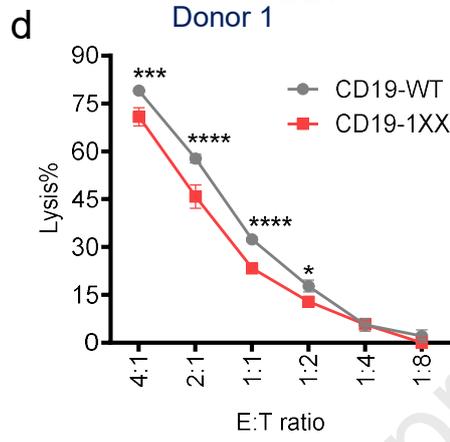

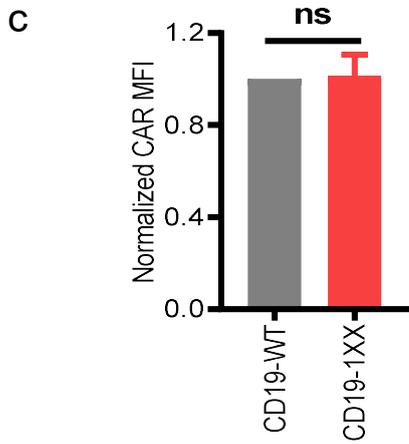

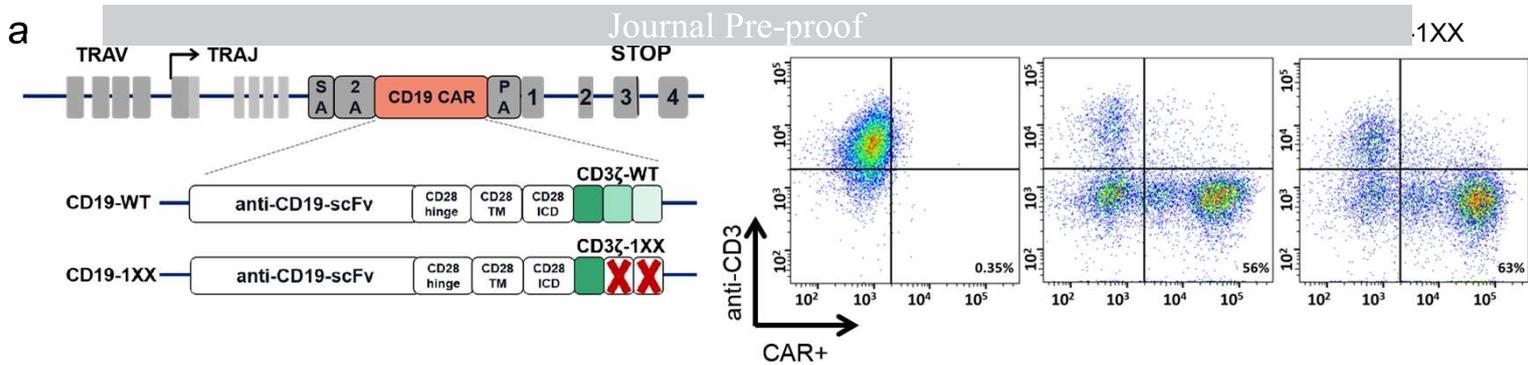

667 (a) Schematic drawings of the constructs. The ZAP70-FRET biosensor was co-expressed with WT  
668 or 1XX CAR in Jurkat T cells. The CAR-T cells were then dropped onto the 3T3<sup>CD19+</sup> cells to  
669 monitor the dynamic ZAP70 kinase activations. (b) Representative images of the ZAP70 biosensor  
670 in the T cells after attaching to the 3T3<sup>CD19+</sup> cell monolayer. Scale bar, 10  $\mu$ m. (c) Time courses of

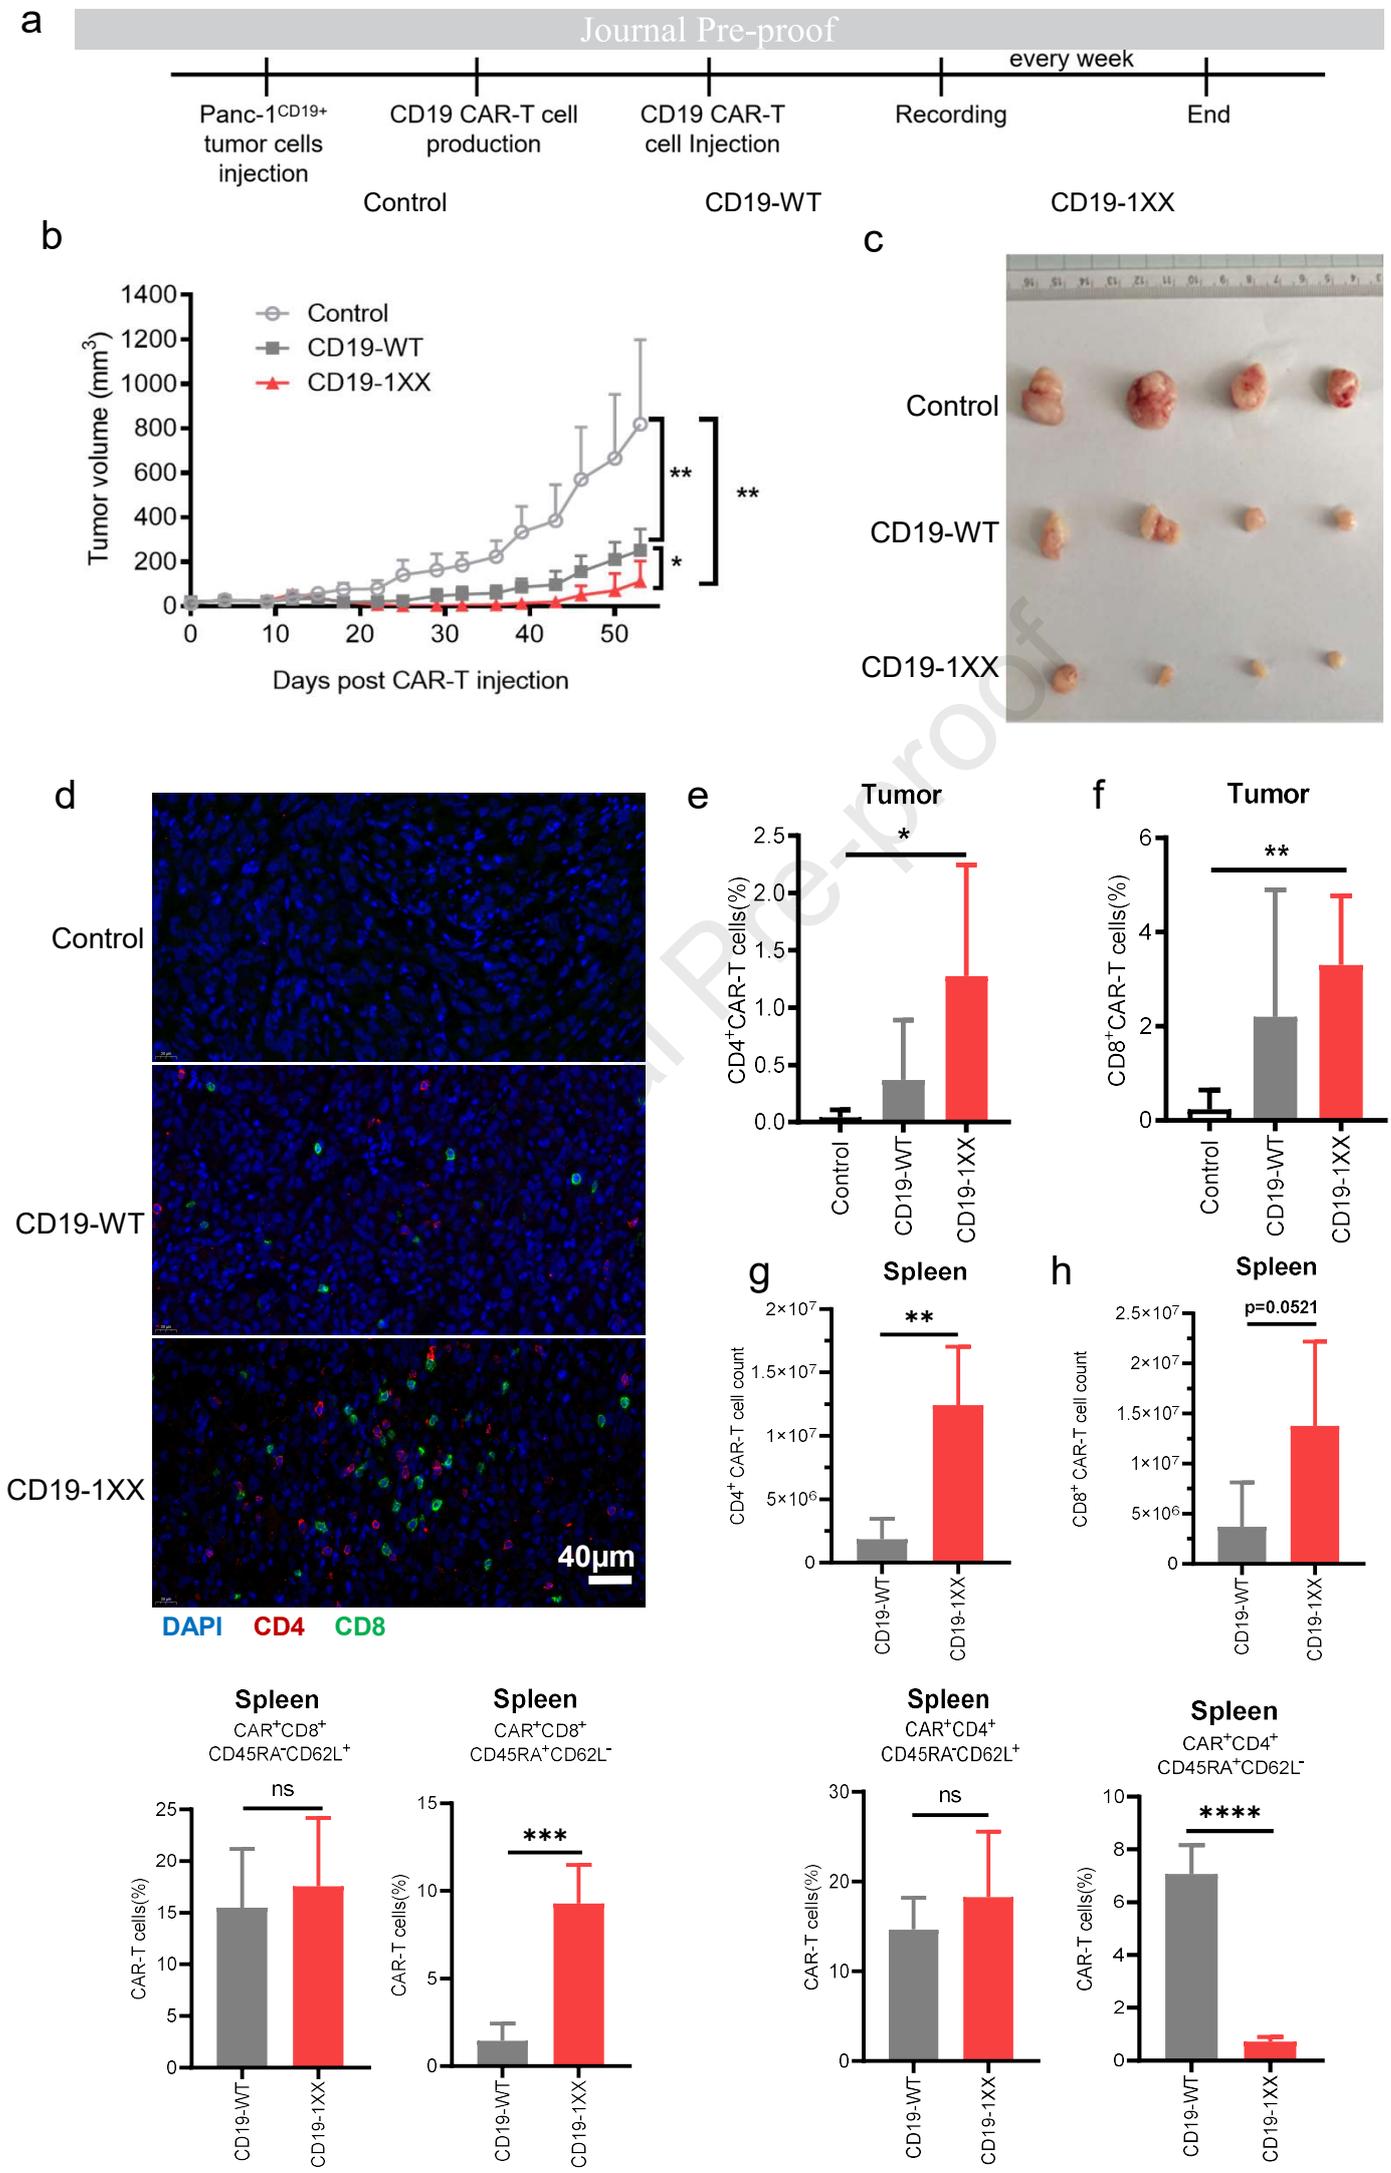

671 the ECFP/FRET ratio of the ZAP70 FRET biosensor in WT or 1XX CAR-T cells (n=13, 13). (d)  
672 Time courses of normalized ECFP/FRET ratio of the ZAP70 FRET biosensor in WT or 1XX CAR-  
673 T cells from 0-5 min (n=13, 13). (e) Normalized ECFP/FRET ratio of the ZAP70-FRET biosensor  
674 in WT or 1XX CAR-T cells at 2 min (n=13, 13, unpaired two-tailed Student's t-test, ns,  $P > 0.05$ ).  
675 (f) Schematic drawings of constructs. The  $\text{Ca}^{2+}$ -FRET biosensor was co-expressed with WT or  
676 1XX CAR in Jurkat T cells. The CAR-T cells were then dropped onto the  $3\text{T}3^{\text{CD}19^+}$  cells to  
677 monitor the dynamic  $\text{Ca}^{2+}$  kinase activations. (g) Representative images of the  $\text{Ca}^{2+}$  biosensor in  
678 T cells after attaching to the  $3\text{T}3^{\text{CD}19^+}$  cell monolayer. Scale bar, 10  $\mu\text{m}$ . (h) Time courses of  
679 FRET/ECFP ratio of  $\text{Ca}^{2+}$ -FRET biosensor in WT or 1XX CAR-T cells (n=27, 22). (i) Time  
680 courses of FRET/ECFP ratio of  $\text{Ca}^{2+}$ -FRET biosensor in WT or 1XX CAR-T cells from 0-3 min  
681 (n=27, 22). (j) FRET/ECFP ratio of  $\text{Ca}^{2+}$ -FRET biosensor in WT or 1XX CAR-T cells at 1.5 min  
682 (n=27, 22, unpaired two-tailed Student's t-test, \*\*,  $P < 0.01$ ). (k) Schematic drawings of constructs.  
683 The Erk-FRET biosensor was co-expressed with WT or 1XX CAR in Jurkat T cells. The CAR-T  
684 cells were then dropped onto the  $3\text{T}3^{\text{CD}19^+}$  cells to monitor the dynamic Erk kinase activations. (l)  
685 Representative images of the Erk biosensor in T cells after attaching to the  $3\text{T}3^{\text{CD}19^+}$  cell monolayer.  
686 Scale bar, 10  $\mu\text{m}$ . (m) Time courses of the normalized FRET/ECFP ratio of the Erk-FRET  
687 biosensor in WT or 1XX CAR-T cells (n=29, 29). (n) Time courses of the normalized FRET/ECFP  
688 ratio of the Erk-FRET biosensor in WT or 1XX CAR-T cells from 0-5 min (n=29, 29). (o)  
689 Normalized FRET/ECFP ratio of the Erk-FRET biosensor in WT or 1XX CAR-T cells at 1.5 min  
690 (n=29, 29, \*\*,  $P < 0.01$ ). All data are mean  $\pm$  SEM.

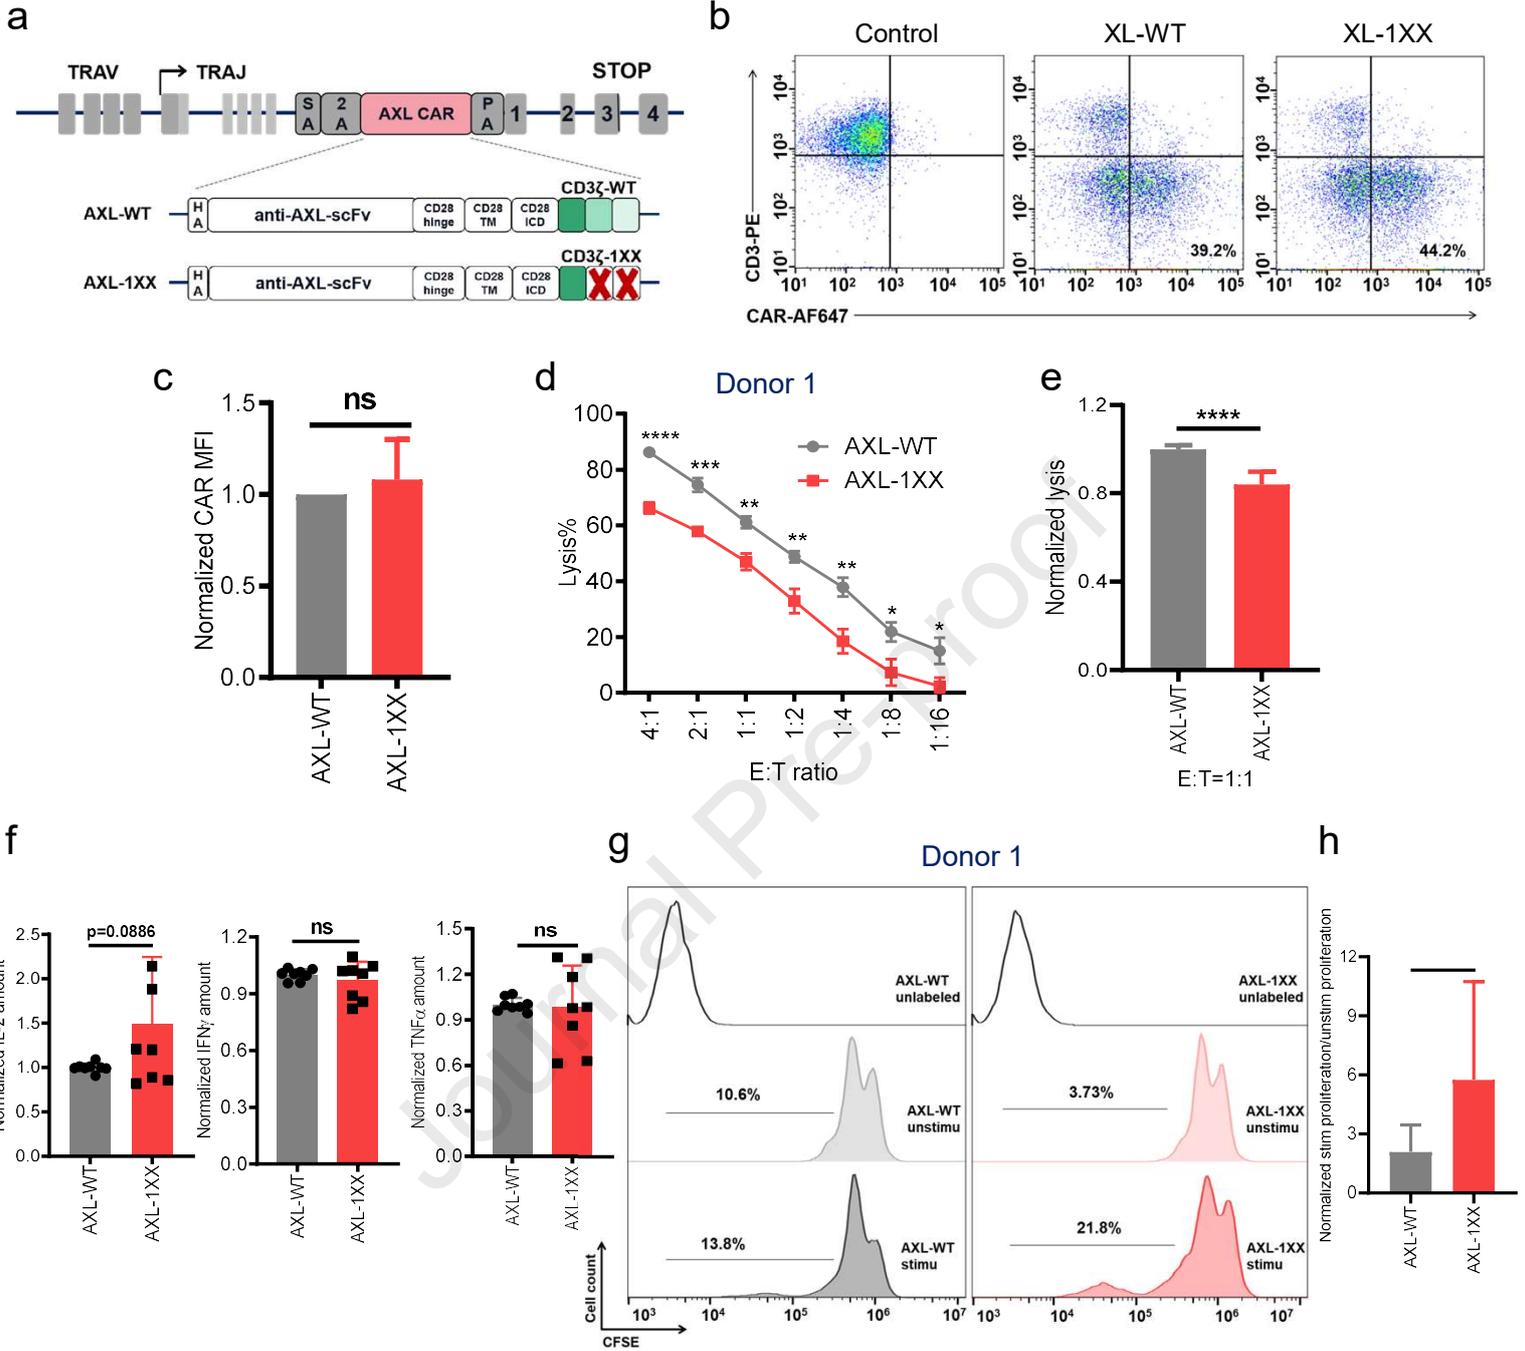

691

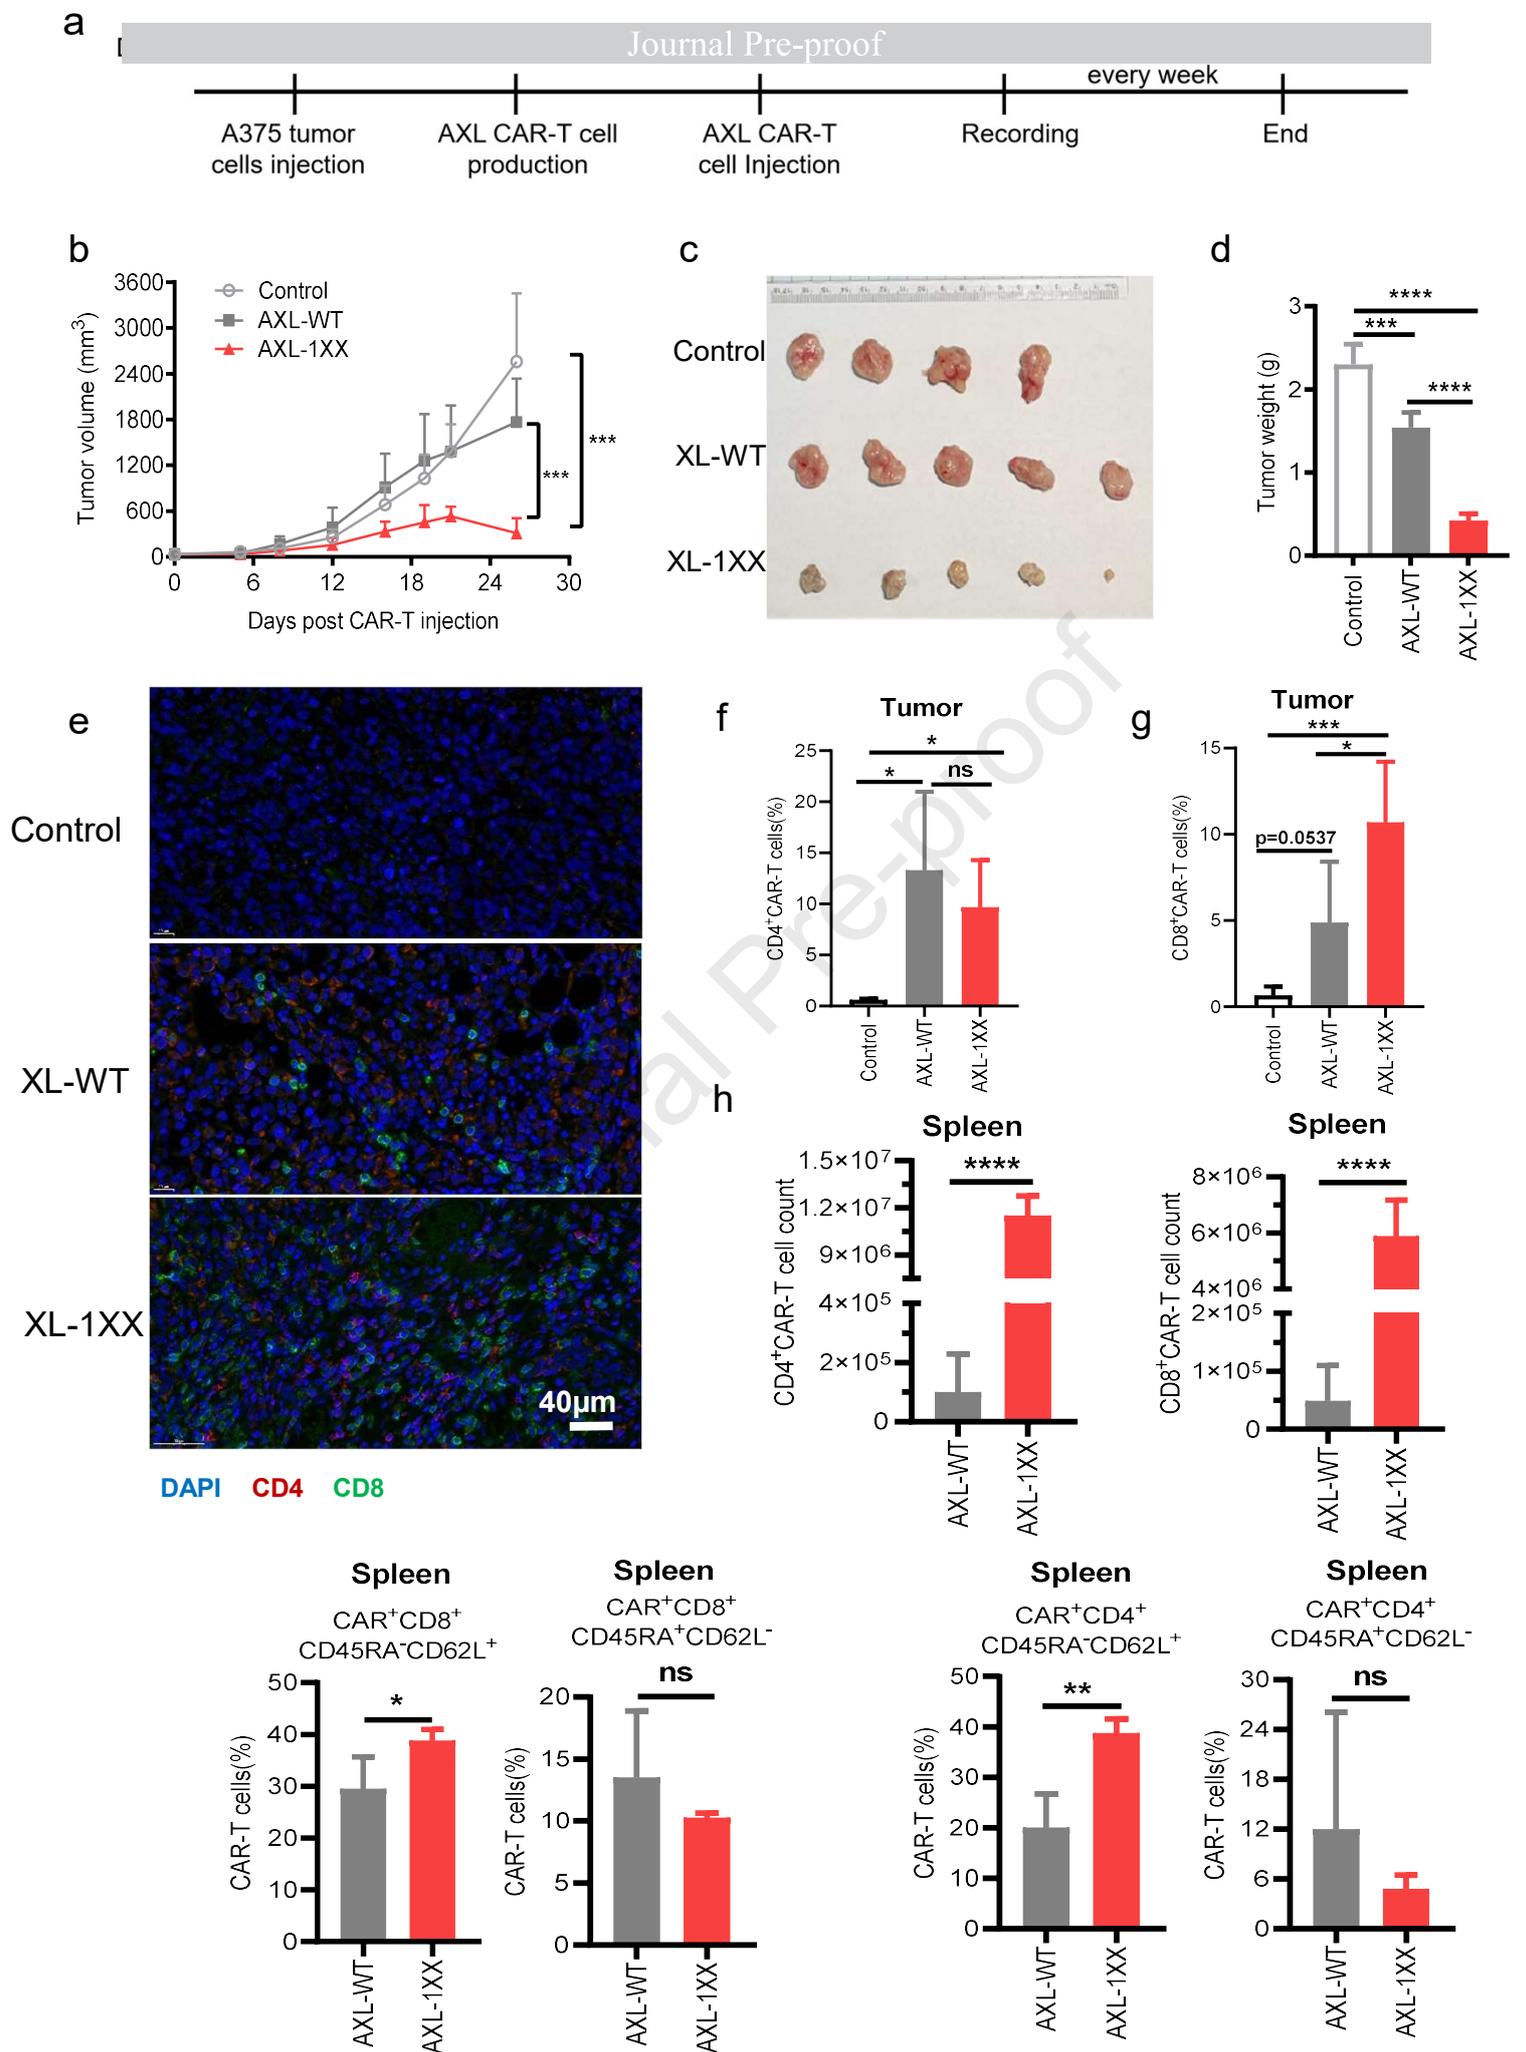

692 Figure 6. Signaling dynamics of the three key molecules downstream WT (left) and 1XX (right)  
693 CAR activation. Upon CAR binding to antigen, Lck phosphorylates CD28 and CD3 $\zeta$  signaling

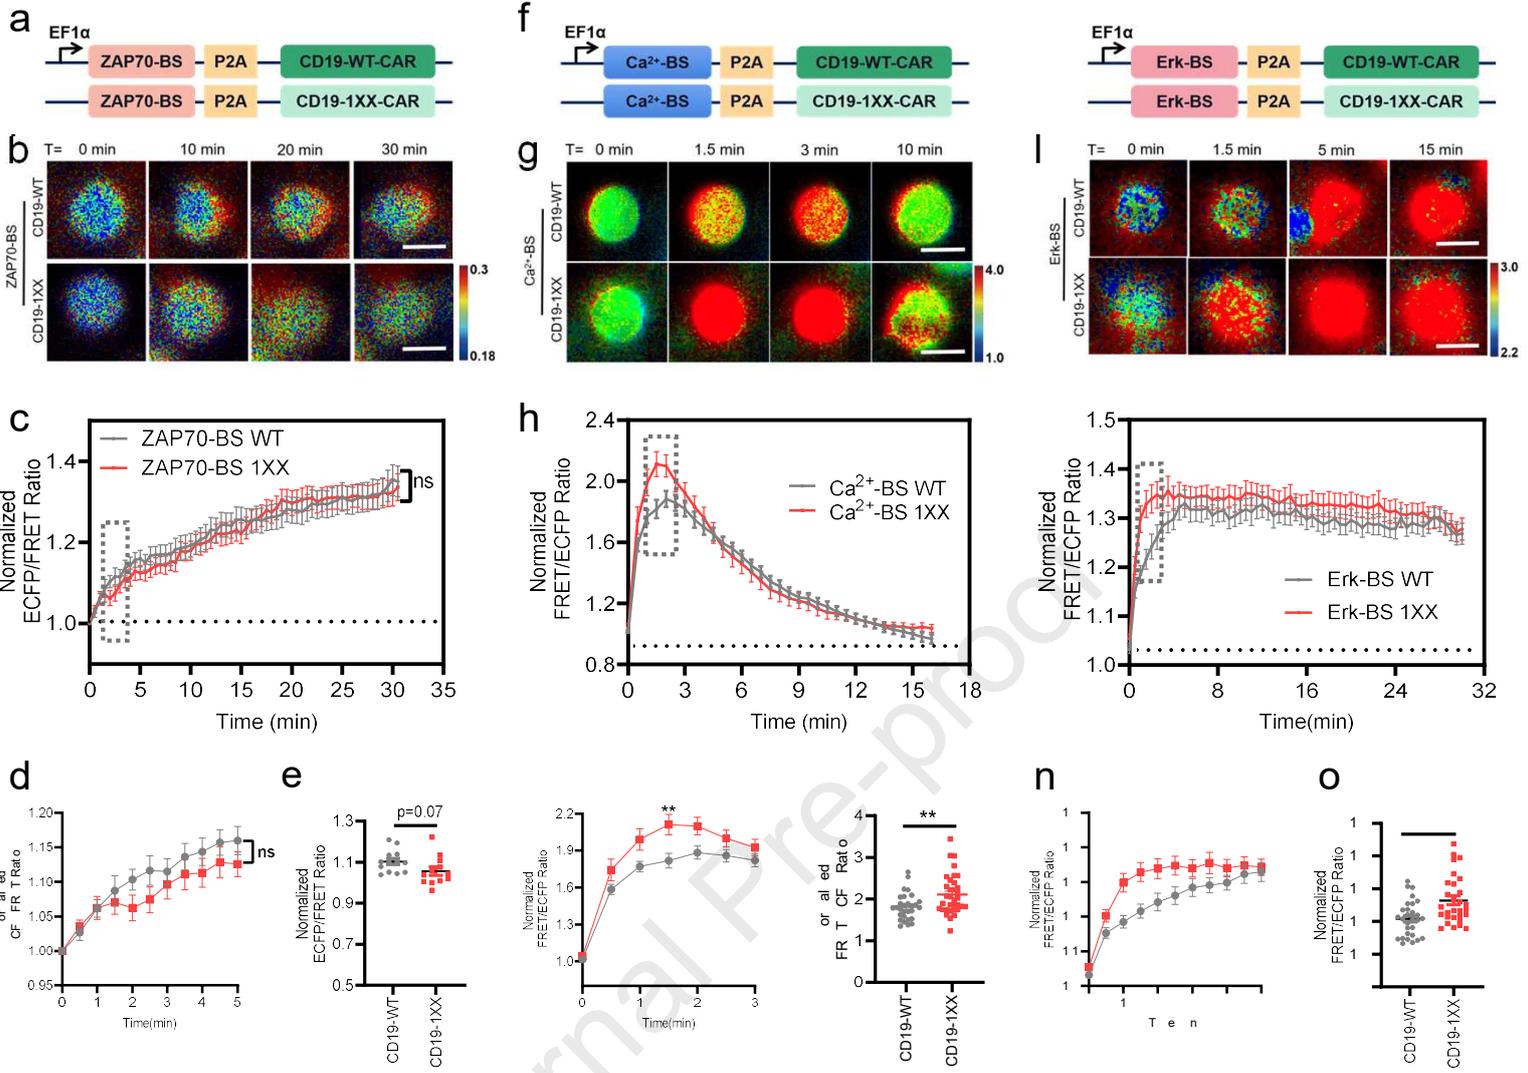

694 domains. Doubly-phosphorylated ITAMs recruit ZAP70 and ZAP70 gets activated by Lck. Singly-  
695 phosphorylated ITAMs recruit Shp1 to inhibit Lck by negative feedback. Activated ZAP70  
696 phosphorylates LAT subsequently activates both  $\text{Ca}^{2+}$  and Erk. Phosphorylated CD28 also  
697 activates  $\text{Ca}^{2+}$  and Erk through the PI3K pathway. In 1XX, reduced ITAMs lead to decreased Shp1  
698 inhibition and possibly enhanced Lck activity. Thus, the PI3K-dependent  $\text{Ca}^{2+}$  and Erk pathway  
699 gets strengthened. Net ZAP70 activity remains unaltered from two opposing effects: decreased  
700 ZAP70 binding from reduced ITAMs, and increased ZAP70 phosphorylation by Lck.

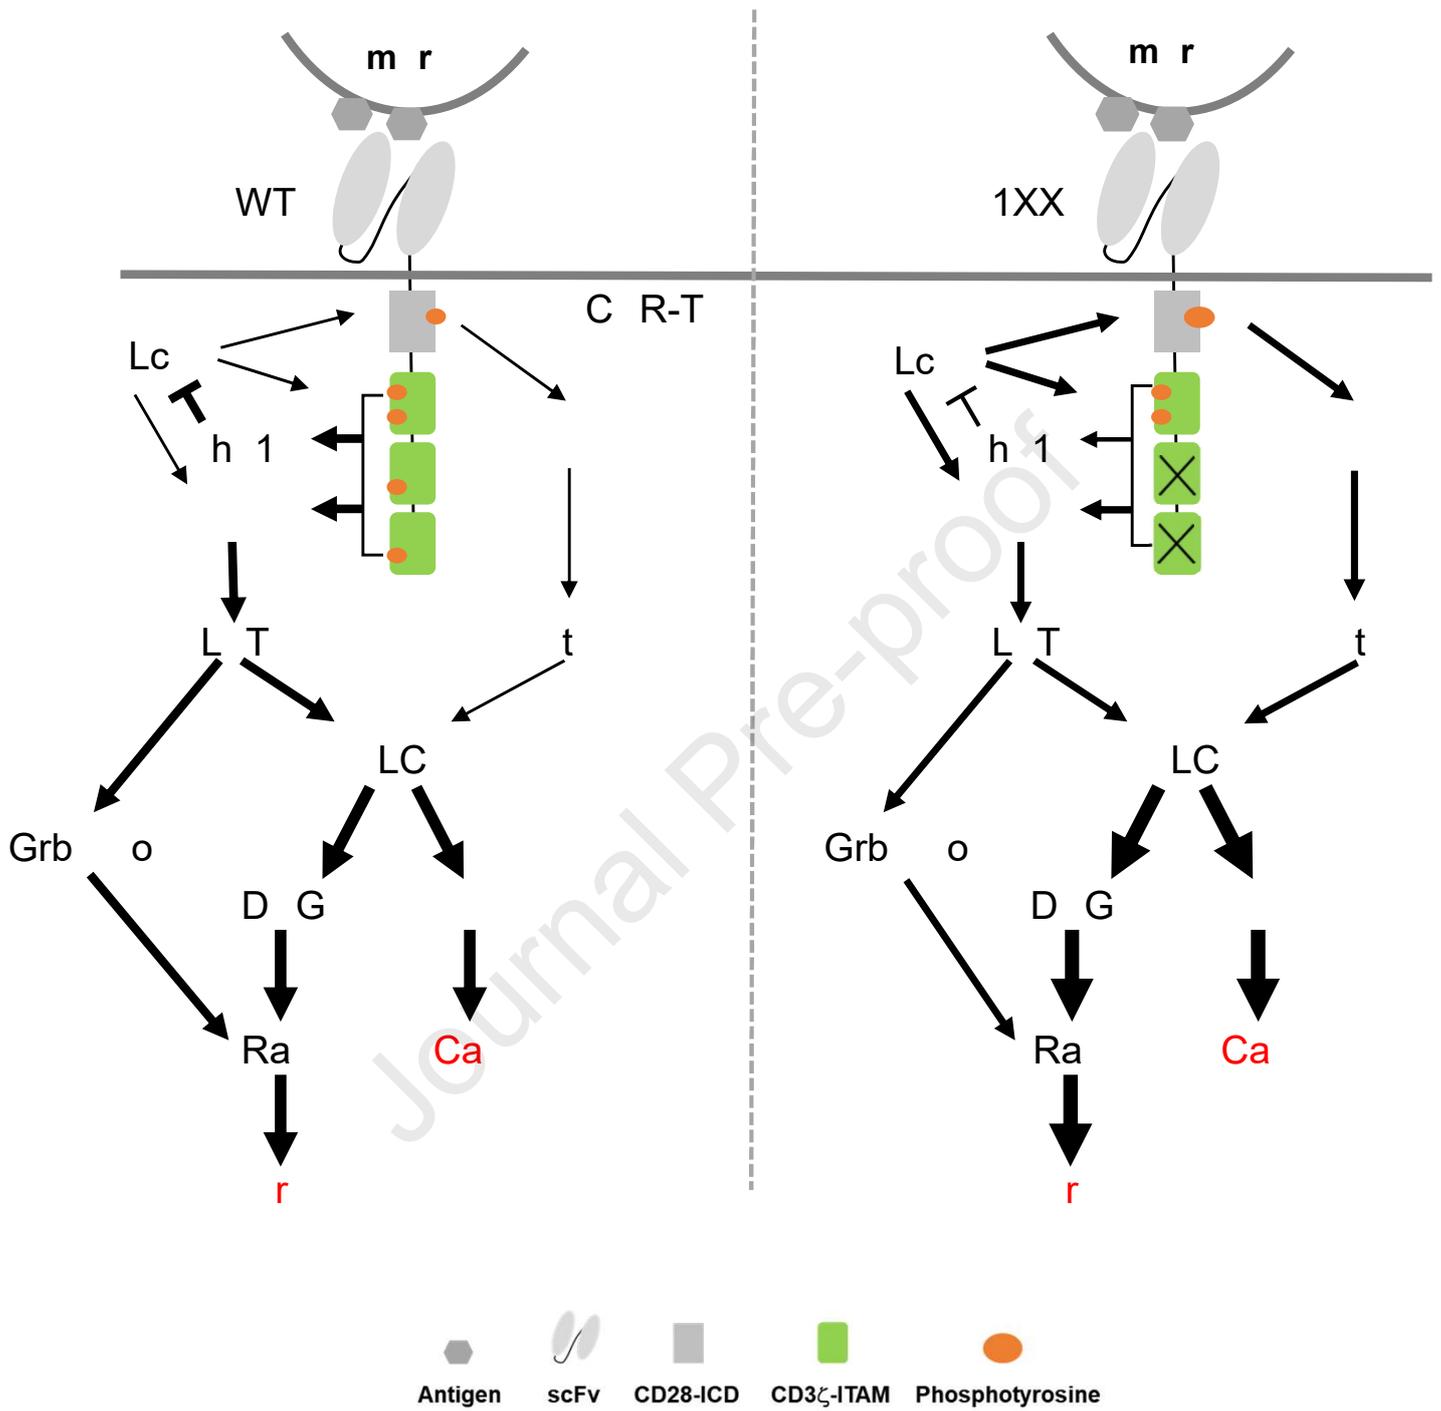

A single-ITAM containing 1XX CAR displayed superior anti-tumor activity in two solid tumor models than WT CAR, paving the way for its clinical applications against solid tumors. Imaging with FRET-based biosensors revealed that 1XX induced higher  $\text{Ca}^{2+}$  elevation and faster Erk activation possibly through reduced Shp1 association and enhanced Lck activation.
